June 13, 2023

# Outline

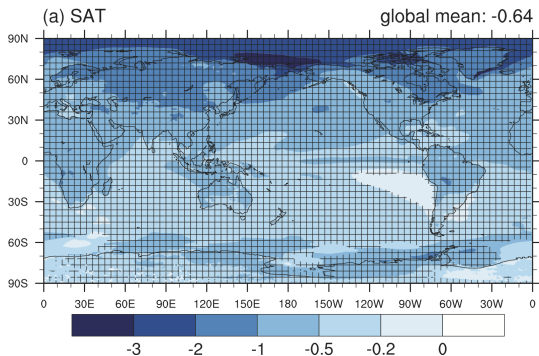

- ① Liang et al., NPJ, 2022: Arctic amplification, and its seasonal migration, over a wide range of abrupt CO<sub>2</sub> forcing
- ② Zhou et al., submitted: Stronger Arctic Amplification Produced by Decreasing, not increasing, CO<sub>2</sub> Concentrations

## Arctic amplification (AA) at high CO<sub>2</sub>

- SSP5-8.5 scenario projects around  $4\times\text{CO}_2$  by 2100 and  $8\times\text{CO}_2$  by 2200
- Most previous AA studies are focused on  $2\times\text{CO}_2$  and  $4\times\text{CO}_2$

# Comparing Scenarios of CO<sub>2</sub> reduction and increase

Jiang et al., 2020

- In the analysis of the atmospheric impact of aerosols, the cooling is the largest in the Arctic regions.

# Anomalous Seasonal Ocean Heat Uptake/Release

Chung et al., 2020

- The seasonality of sea ice directly influences the thermal storage of the oceans, leading to pronounced seasonality in the energy transfer mechanisms within the Arctic region.

# Model Runs

Model:

- **CESM1-LE:** 30-level CAM5 (1°) and 60-level POP2 (1°)

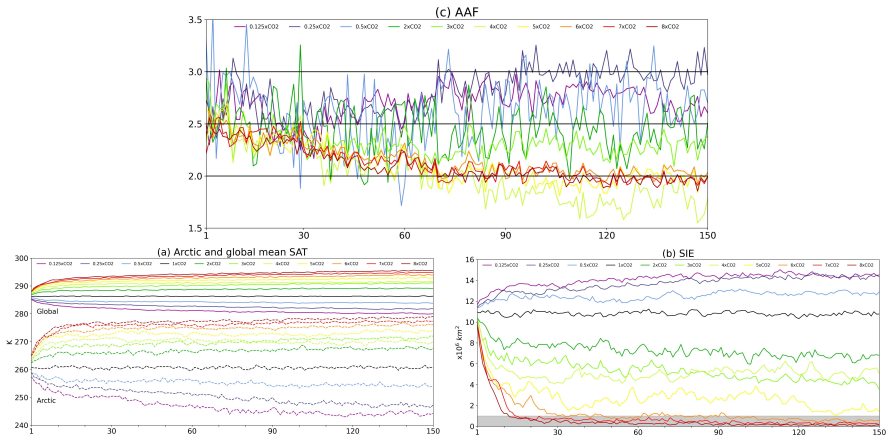

Experiments

- **Fully coupled abrupt:** 1/8×, 1/4×, 1/2×, 2×, 3×, 4×, 5×, 6×, 7×, 8×CO<sub>2</sub> for 150 years
- **Slab ocean:** abrupt 1×, 2×, 3×, 4× 5×, and 6×CO<sub>2</sub> for 60 years

# AAF weakens at higher CO<sub>2</sub> levels

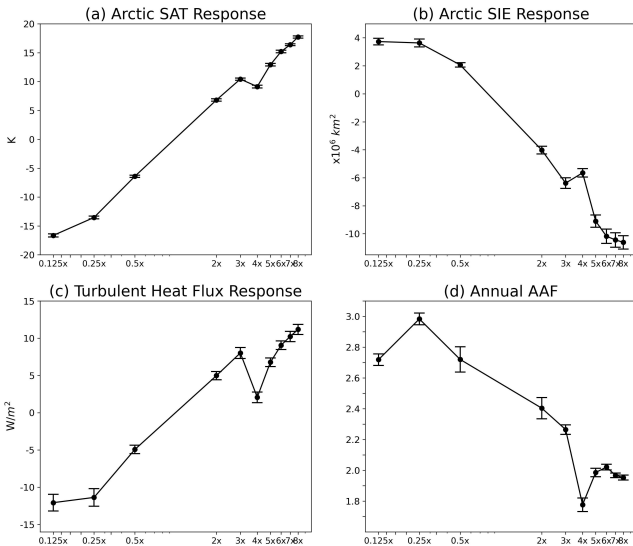

# The cold AAFs are larger than the warm AAFs

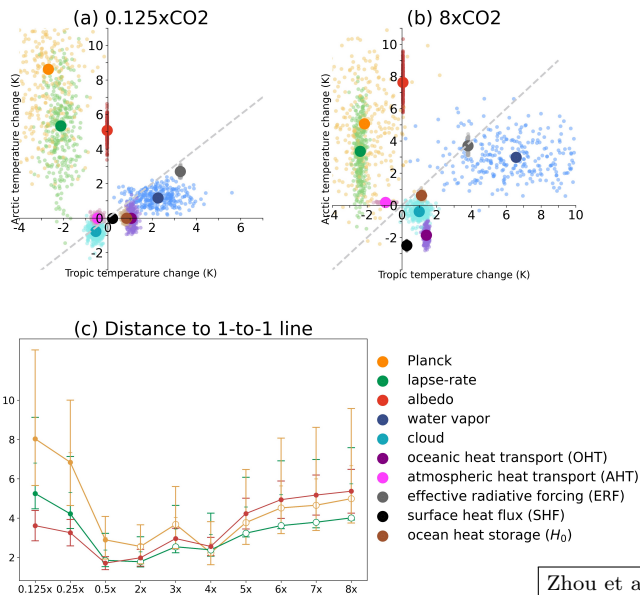

Zhou et al., submitted

# Asymmetric Responses in Arctic Amplification

Zhou et al., submitted

# PL, LR and AL feedbacks are main contributors to AAF

# Seasonal migration of AAF peak

(a) Arctic (60° N) SAT response

(b) Arctic (60° N) SIE response

(c) Turbulent Heat Flux Response (60° N)

(d) AAF (60° N)

● 0.125xCO2 
 ● 0.25xCO2 
 ● 0.5xCO2 
 ● 2xCO2 
 ● 3xCO2 
 ● 4xCO2 
 ● 5xCO2 
 ● 6xCO2 
 ● 7xCO2 
 ● 8xCO2

- AAF peak in CO<sub>2</sub> increase moves from November to December of January
- CO<sub>2</sub> decrease levels cannot migrate the peak of AAF earlier than October

# Seasonality for feedbacks, ERF, AHT, and OHT

(a) Seasonal Migration of SAT change

(b) Seasonal Migration of Water Vapor Feedback

(c) Seasonal Migration of ERF

(d) Seasonal Migration of Lapse Rate Feedback

(e) Seasonal Migration of Cloud Feedback

(f) Seasonal Migration of OHT

(g) Seasonal Migration of Planck Feedback

(h) Seasonal Migration of Albedo Feedback

(i) Seasonal Migration of AHT

— 0125xCO2 — 025xCO2 — 05xCO2

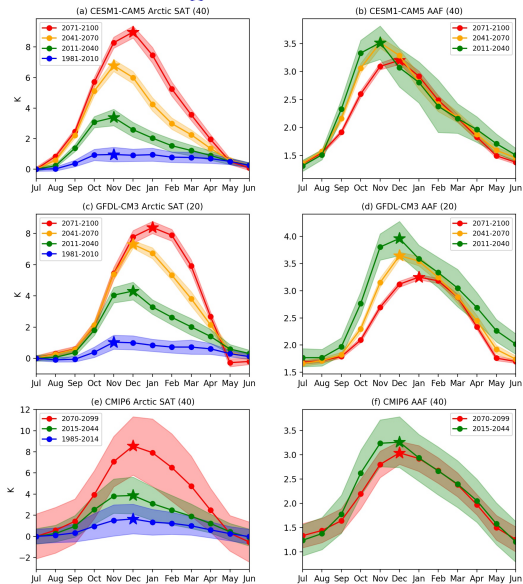

— 2xCO2 — 3xCO2 — 4xCO2 — 5xCO2

— 6xCO2 — 7xCO2 — 8xCO2

Zhou et al., submitted

# Seasonal migration in 21st century

## Summary

- Weaker AA at higher CO<sub>2</sub> levels
- **Decreasing** CO<sub>2</sub> concentrations produce stronger AA than **increasing** CO<sub>2</sub> concentrations
- **Peaks of warm AA** shift gradually from November to December or January as the CO<sub>2</sub> forcing strength enhances
- The seasonal shift in AA emerges in the 21st century in high-CO<sub>2</sub> emission scenario simulations
- **Peaks of cold AA** are locked in October bounded by the maximum sea-ice increase in September.
- Planck, lapse-rate, and albedo feedbacks are the main contributors to producing AAs forced by CO<sub>2</sub> increase and reduction
